Segmentation as Labeling

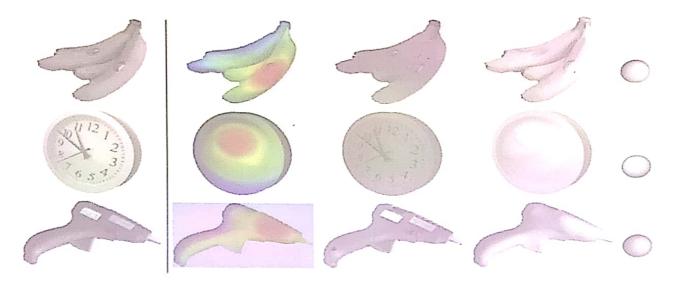

Normal/Shape Estimation

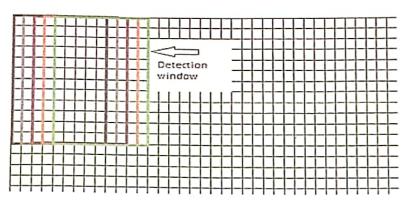

Estimate normal and albedo at every pixel: What should we optimize?

Image Restoration/Enhancement

Detection and Recognition

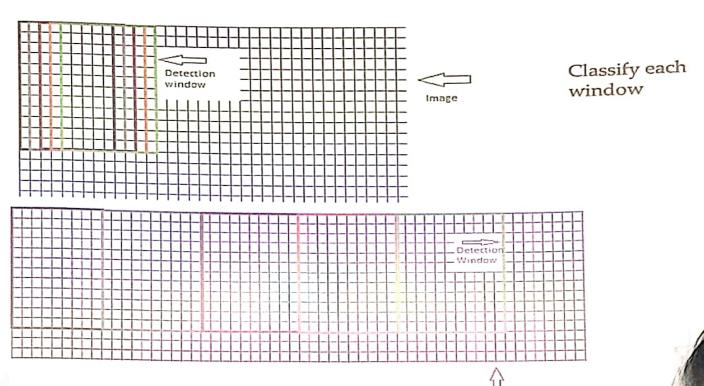

Classify each window

Detection and Recognition

Image

Face Detection using Eigenfaces

- Given an unknown image Γ

Step 1: compute $\Phi = \Gamma - \Psi$

Step 2: compute $\hat{\Phi} = \sum_{i=1}^{K} w_i u_i$ $(w_i = u_i^T \Phi)$ (where $||u_i|| = 1$)

Step 3: compute $e_d = \|\Phi - \hat{\Phi}\|$

Step 4: if $e_d < T_d$, then Γ is a face.

The distance e_d is called distance from fac

Face Detection using Eigenfaces

Given an unknown image Γ

Step 1: compute $\Phi = \Gamma - \Psi$

Step 2: compute $\hat{\Phi} = \sum_{i=1}^{K} w_i u_i$ $(w_i = u_i^T \Phi)$ (where $||u_i|| = 1$)

Step 3: compute $e_d = ||\Phi - \hat{\Phi}||$

Step 4: if $e_d < T_d$, then Γ is a face.

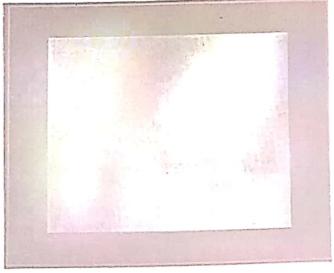

The distance e_d is called distance from face space (dffs)

Distance from Face Space

Visualize dffs: $e_d = \|\Phi - \hat{\Phi}\|$

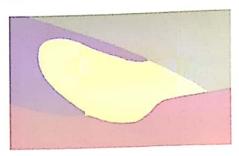

Real-time Face Detection: Viola and Jones

The Task of Face Detection

Basic Idea

Slide a window across image and evaluate a face model at every location

How Many Windows (Speed)

1280×1024 image; 24×24 to 1024×1024 windows

- # of Windows?
 - o 1.3 million locations
 - o 18 scales/window sizes at 1.25 multiples
 - o 14.5 million potential face candidates
 - o Features to be extracted for each candidate window

Accuracy (FPR)

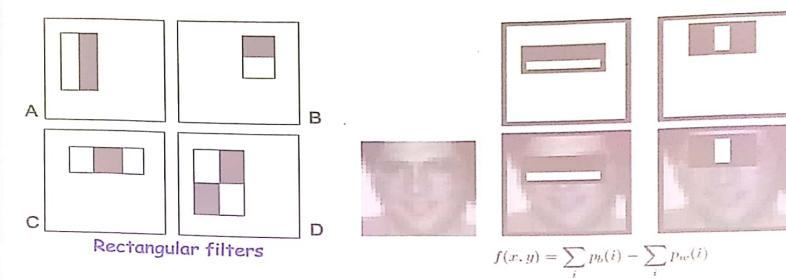

- Classify each as face or non-face
 - o What should be the accuracy (False Positive Rate)?
 - Faces are rare: 0-10 per image
 - For computational efficiency, we should try to spend as little time as possible on the non-face windows
 - To avoid having a false positive in every image, the false positive rate has to be less than 10-6

The Viola/Jones Face Detector

- A seminal approach to real-time object detection
- Key ideas
 - Integral images for fast feature evaluation
 - Boosting for feature selection
 - Attentional cascade for fast rejection of non-face windows
- P. Viola and M. Jones. Rapid Object Detection using a Boosted Cascade of Simple Features. CVPR 2001.
- P. Viola and M. Jones. Robust Real-Time Face Detection. IJCV 57(2), 2004.

Image Features

Local features: Subtract sum of pixels in white area from the sum of pixels in black area; 2-rectangle features (A and B), 3-rectangle feature (C) and 4-rectangle feature (D)

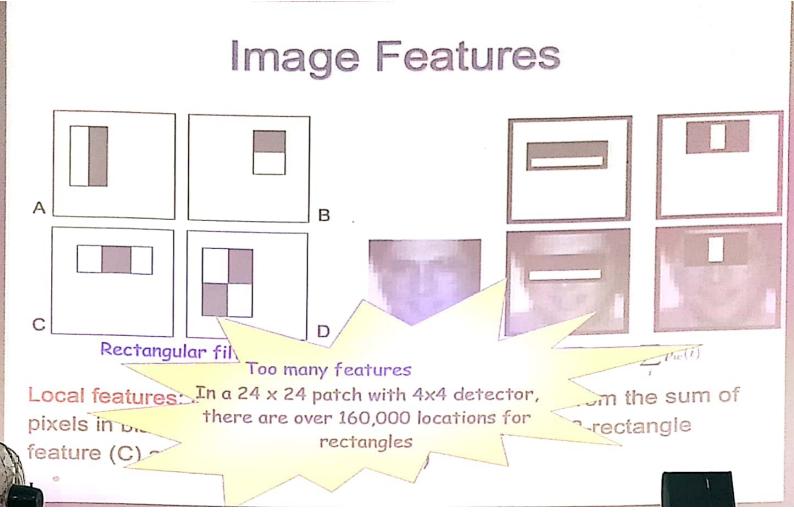

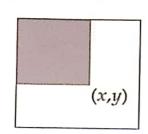

Image Features

- Integral Image: An intermediate representation of the image for rapid calculation of rectangle features
- s(x,y) is the cumulative row sum, s(x,-1) =0 and ii(-1, y) = 0; the integral image can be computed in one pass over the original image

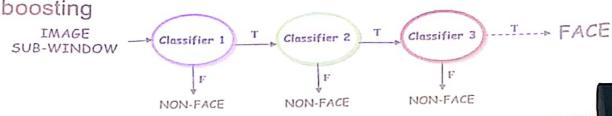

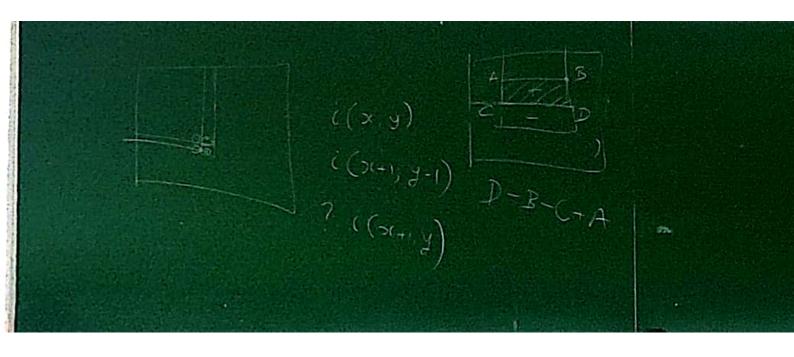

$$ii(x, y) = \sum_{x' \le x, y' \le y} i(x', y'),$$

$$s(x, y) = s(x, y - 1) + i(x, y)$$

$$ii(x, y) = ii(x - 1, y) + s(x, y)$$

Reject non-face windows through a cascade of classifiers and

Example

IMAGE

0	1	1	1
1	2	2	3
1	2	1	1
1	3	1	0

INTEGRAL IMAGE

0	1	2	3
1	4	7	11
2	7	11	16
3	11	16	21

Rectangle Features from Integral Image

- Rectangle features are somewhat primitive and coarse, they are sensitive to presence of edges, bars, and other simple structure
- Generating a large no. of these features and their computational efficiency compensates for this.

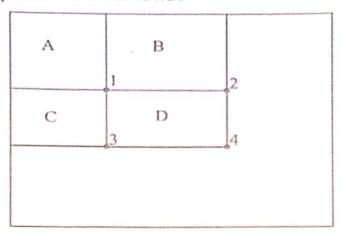

Figure 3. The sum of the pixels within rectangle D can be computed with four array references. The value of the integral image at location 1 is the sum of the pixels in rectangle A. The value at location 2 is A+B, at location 3 is A+C, and at location 4 is A+B+C+D. The sum within D can be computed as 4+1-(2+3).

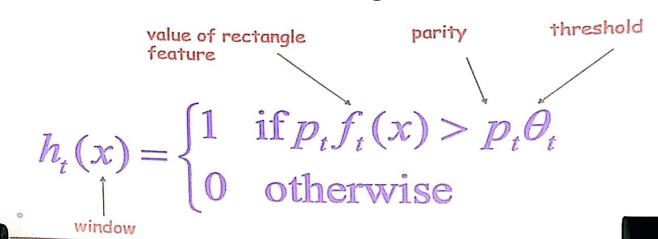

Face Detector

- Scan the input at many scales
- Starting at the base scale in which faces are detected at 24x24 pixels, a 384x288 pixel image is scanned at 12 scales each a factor 1.25 larger than the last
- Any rectangle feature can be evaluated at any scale and location in a few operations
- Face detection @15 fps for the entire image

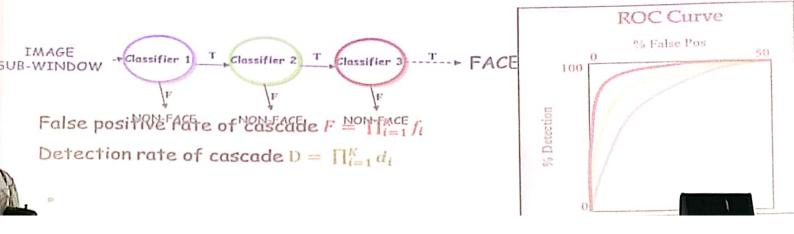

Weak Learners for Face Detection

- Hypothesis: A very small no. of 160K (x4) features for each image sub-window can be formed to find an effective classifier (face vs. non-face)
- AdaBoost is used both to select the features and train the classifier
- Weak learner: a single rectangle feature that best separates
 positive and negative examples; so weak classifier is a thresholded
 single feature (can be viewed as a single node decision tree)

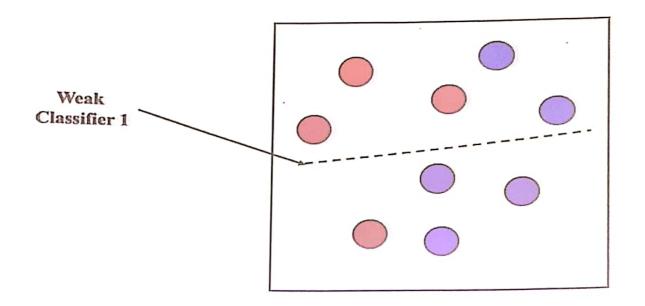

Cascade of classifiers

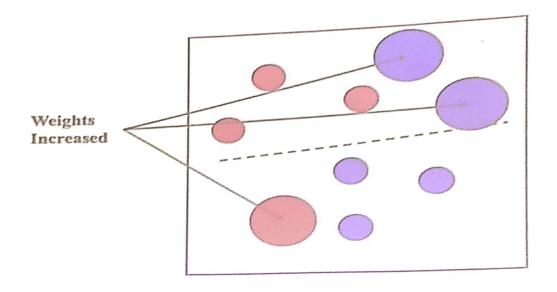

- Train each classifier with increasing number of features until the target false positive and detection rates are achieved
- Use false positives from current stage as the negative training examples for the next stage
- Classifiers are progressively more complex and have lower false positive rates

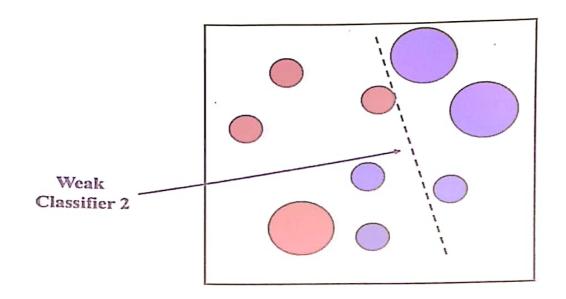

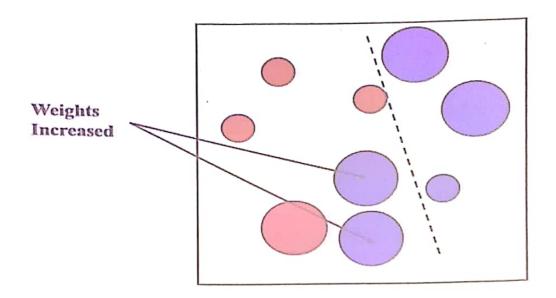

Boosting

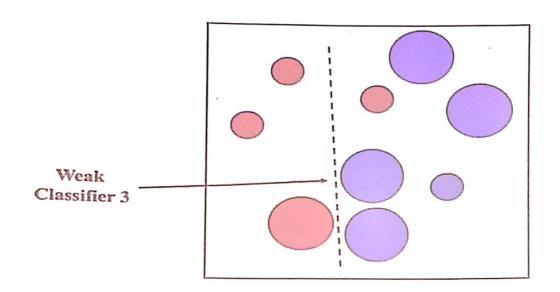

- Training set contains face and nonface examples
 - Initially, with equal weight
- For each round of boosting:
 - Evaluate each rectangle filter on each example
 - · Select best threshold for each filter
 - · Select best filter/threshold combination
 - Reweight examples
- Computational complexity of learning: O(MNK)
 - M rounds, N examples, K features

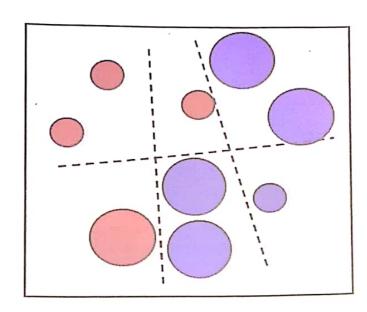

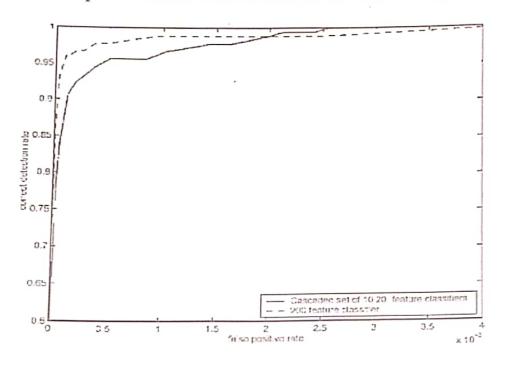

Final classifier is a combination of weak classifiers

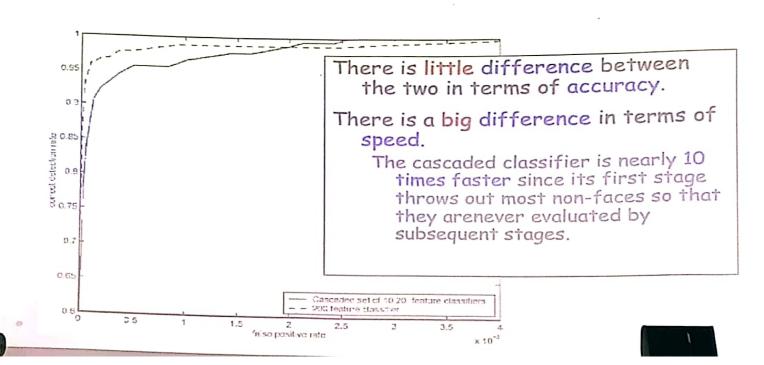

ROC Curves Cascaded Classifier to Monolithic Classifier

Speed of cascade classifier is 10 times faster

ROC Curves Cascaded Classifier to Monolithic Classifier

Face Detection System

- Training Data
 - 5000 faces
 - All frontal, rescaled to 24x24 pixels
 - 9500 million non-faces
 - Faces are normalized
 - Scale, translation
- Many variations
 - Across individuals
 - Illumination
 - · Pose

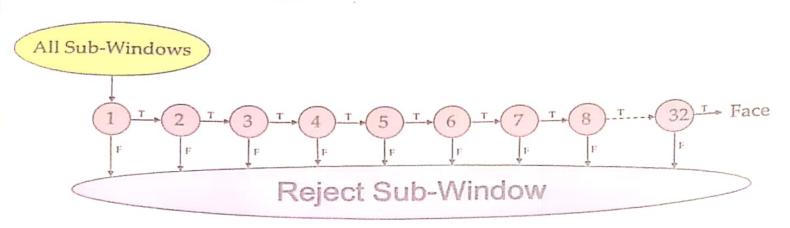

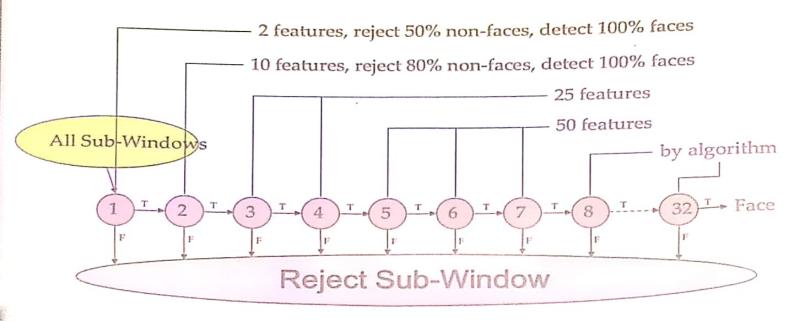

Structure of the Detector Cascade

Increasingly complex classifiers in cascade

- 32 stages
- included a total of 4297 features

Structure of the Detector Cascade

Feature Selection

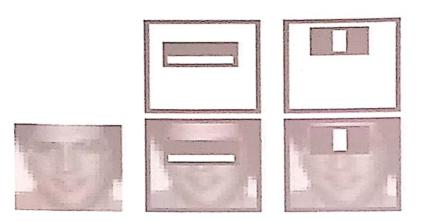

Figure 5: The first and second features selected by AdaBoost. The two features are shown in the top row and then overlayed on a typical training face in the bottom row. The first feature measures the difference in intensity between the region of the eyes and a region across the upper cheeks. The feature capitalizes on the observation that the eye region is often darker than the cheeks. The second feature compares the intensities in the eye regions to the intensity across the bridge of the nose.

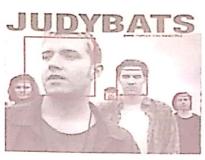

Speed of the Final Detector

- On a 700 Mhz Pentium III processor, the face detector can process a 384 x288 pixel image in about ".067 seconds"
 - 15 times faster than previous detector of comparable accuracy (Rowley et al., 1998)
- Average of 8 features evaluated per window on test set

Output of Face Detector on Test Images

Summary: Viola/Jones detector

- Rectangle features
- Integral images for fast computation
- Boosting for feature selection
- Attention cascade for fast rejection of negative windows
- Can be made scale invariant (image pyramids)
- Generic Method: other detectors with same approach

Summary: Viola/Jones detector

- Rectangle features
- Integral images for fast computation
- Boosting for feature selection
- Attention cascade for fast rejection of negative windows
- Can be made scale invariant (image pyramids)
- Generic Method: other detectors with same approach
- · Cons:
 - Needs special training for non-frontal faces
 - Sensitive to lighting conditions
 - Multiple detections from the same face (overlapping)
